

FL 13: Explain It Like You Built It

The piece I picked

How the hex codes from my identity kit turn into usable Tailwind classes like bg-accent or text-accent on my components.

Plain words explanation

The :root block is just where I store my raw colors as CSS variables, that part has nothing to do with Tailwind, any website does this. The @theme inline block is where Tailwind actually gets involved, it looks for any variable named --color-something and, when it finds one, automatically builds three utility classes from it: bg-something, text-something, border-something. So when I wrote --color-accent: var(--accent); in that block, I never had to manually create bg-accent, Tailwind generated it for me just because I followed that naming pattern.
